

We need lithium for clean energy, but Rio Tinto's planned Serbian mine reminds us it shouldn't come at any cost

Jadar lithium mine proposed by global mining giant Rio Tinto. The project, Rio Tinto's flagship renewable energy initiative, is set to become the largest lithium project in the European Union.

Lithium is a crucial component of energy storage, both for renewable energy technologies and electric vehicles. Forecast demand has prompted efforts by companies and governments worldwide to tap into this market - a scramble dubbed the "white gold rush".

As lithium projects have multiplied across Australia, Europe, Latin America and the US in recent years, so too have concerns over their environmental and social impacts.

Communities near proposed and existing lithium mines are some of the loudest opponents.

In a town near the proposed mine in Serbia, a banner reads: "No mine, yes life".

Lithium extraction serves legitimate global environmental needs. But the industry must not ignore local social and environmental risks, and community voices must be included in decision making. The harsh lessons of mining to date need not be learned again in new places.

Weighing the risks

According to the latest estimates, the world's resources of lithium sit at 86 million tonnes, a number that continues to grow as new deposits are found every year. Australia is the main producer of lithium, where it's mined from hard rock called "spodumene". The largest deposits are found in South America, where lithium is extracted from brines underneath salt flats.

In many cases, lithium mines are relatively new operations, yet complex and adverse social and environmental impacts have already been observed. More research and better targeted policy are needed to help understand and manage the socio-environmental impacts.

In Chile, lithium has been mined since the 1980s. It has been shown to interfere with cultural practices of local Indigenous communities, alter traditional economic livelihoods and exacerbate the fragility of surrounding ecosystems.

The Jadar lithium project is operated by Rio Sava, a subsidiary of Rio Tinto. It's expected to become one of Serbia's largest mines, occupying around 387 hectares, and contribute to at least 1% of Serbia's GDP.

An environmental impact study commissioned by Rio Tinto, and obtained by Reuters, found the project would cause "irredeemable damage" to the environment, concluding the project should not go ahead. Environmental impacts are expected for any mine proposal. Yet some are manageable, so such a grave assessment in this case is not encouraging.

The extent to which a project shows best practice in mine management can depend on pressure from communities, investors and governments. Promises to adhere to all

We need lithium for clean energy, but Rio Tinto's planned Serbian mine reminds us it shouldn't come at any cost

regulations are a common response from the industry.

But as we're seeing in Chile, significant environmental damage and socio-environmental impacts can still occur within established regulations. Here, communities living on the salt flats are concerned about the effect of removing groundwater for lithium extraction on their livelihoods and surrounding ecosystems.

Communities near the Jadar Mine project hold similar concerns. They have gathered in formal organisation to reject the project and stage demonstrations. A petition against the project has gained over 130,000 signatures, and a report by the Serbian Academy of Arts and Sciences has protested the project's approval.

The communities fear the potential risks of air and waterborne pollution from the lithium mine, destruction of biodiversity, and the loss of land to mine infrastructure. These risks could affect the livelihoods of local landholders, farmers and residents.

Of particular concern is that the proposed locations for mine waste (tailings) are in a valley prone to flash flooding and may lead to toxic waste spills. This previously occurred in the same region when the abandoned Stolice antimony mine flooded in 2014. Rio Tinto has said it will try to mitigate this risk by converting the liquid waste into so-called "dry cakes".

In response to this article, a Rio Tinto spokesperson said it has been working through the project requirements for 20 years, with a team of over 100 domestic experts studying the possible cumulative impacts in accordance with Serbian law, adding:

Can we decarbonise without sacrifice?

The Jadar Mine project is touted for its potential to bring significant profits to both Rio Tinto and the Serbian state, while helping usher in the era of decarbonisation.

Rio Tinto plans to begin construction by 2022, "subject to receiving all relevant approvals, permits and licences and ongoing engagement", with first saleable production expected in 2026.

But relatively fast timelines like this can sometimes be a sign of regulatory governance instability, including weak regulatory frameworks or regulatory capture (when agencies are increasingly dominated by the interests they regulate). We have seen this in Guyana, Peru and Brazil.

In Australia, Rio Tinto's recent destruction of the culturally invaluable Juukan Gorge — which, notably, occurred legally — also demonstrates regulatory governance risks.

Rio Tinto's spokesperson said its Environmental Impact Assessment process includes a public consultation period including, for example, meetings with non-government organisations, adding:

We need lithium for clean energy, but Rio Tinto's planned Serbian mine reminds us it shouldn't come at any cost

Although the Serbian government indicated that it's prepared to hold a referendum to find out the will of citizens about the Jadar mine project, the community protests suggest the project hasn't obtained any social license to operate.

A "social license to operate" is, despite its corporatised name, increasingly key to sustainable or responsible mining projects. It centres on ongoing acceptance by stakeholders, the public, and local communities of a company's standard business practices. Building such trust takes time, and a social license is only a minimum requirement.

In Argentina, for example, Indigenous communities living near the lithium mines have developed their own protocol for giving their informed consent.

Similarly, processes of community-based impact assessment or self-government structures led by First Nations in Canada offer insight into potential collaborative relationships.

These processes cannot be rushed to ensure voices are heard, rights are respected, and environmental protection is possible.

A new frontier

Like many other communities negotiating proposed mine projects, local communities and residents in [Serbia](#) should not become another zone of sacrifice, shouldering the socio-environmental costs of supporting a [renewable energy transition](#).

Lithium deposits are often seen as "new frontiers" in the places they're discovered. Yet we must learn from historical lessons of frontier expansion, and remember that places imagined as "undiscovered" aren't actually empty.

The people who live there must not bear the brunt of a so-called "green" future.
